### PATHOLOGY REPORT

Clinical Information.	Right arm swelling, suspected of hemangioma.
Nature of specimen.	Biopsy.

#### GROSS:

Soft tissue fragment measured 4x3x2 cm, totally embedded.

#### MICROSCOPIC:

Nodal tissue showing near total loss of the normal nodal pattern and replacement by a rather polymorphic infiltrate formed dominantly of histiocytes, activated small and intermediate-sized lymphocytes and few plasma cells with many scattered mono, binucleated giant cells. Lymph node shows incomplete fibrous septa. Possibilities include Hodgkin's disease, Hodgkin's-like anaplastic large cell lymphoma, peripheral T-cell lymphoma (NOS) and T-cell rich, large B-cell lymphoma (TCR-LBCL). Immunophenotyping (CD15, CD30, CD20, CD3, EMA, OCT-2, MUM1) is needed.

#### DIAGNOSIS:

##### Lymph node, excision biopsy:

- Atypical polymorphic infiltrate, suspicious of lymphoma.
- Recommend for confirmation and definitive typing by marker study.

#### Pathologist

Prof. Dr. Neveen Tahoun, MD, PhD
