## PATHOLOGY REPORT

Clinical Information.	Gingival biopsy.
Nature of specimen.	Incisional biopsy.

### GROSS:

Soft tissue fragments collectively measured 0.7x0.6x0.3 cm, totally embedded.

### MICROSCOPIC:

Sections show hyperplastic stratified squamous epithelium with parakeratosis and irregular rete ridge elongation. A dense, band-like chronic inflammatory infiltrate—predominantly lymphocytic with scattered plasma cells—obscures the epithelial-connective tissue interface via basal cell liquefactive degeneration. No dysplasia or malignancy is identified.

### DIAGNOSIS:

#### Gingival biopsy:

- Lichenoid tissue reaction, consistent with a lichenoid contact lesion.
- Negative for malignancy.

### Pathologist

Prof. Dr. Neveen Tahoun, MD, PhD
